Introduction

Introduction

Classes as data structures with methods

> TEAM INFDEV

Lecture topics

- In this lecture we will "close the circle" of data structures and functions
- We will show how it is possible to form a new, even more powerful abstraction
- We will define classes as the joining of functions and data structures

Classes as data structures with methods

> TEAM INFDEV

Problem discussion

Problem discussion

Classes as data structures with methods

> TEAM INFDEV

Introduction

- Functions on lists always take a list as input
- This list is understood as the main subject of the computation
- We would like to create a stronger visual and semantic link between the subject of a computation and the computation itself

Problem discussion

Classes as data structures with methods

> TEAM INFDEV

Examples

- length of a list
- sum of a list
- find in a list a given element
- map of a list wrt some transformation
- ...

Classes as data structures with methods

> TEAM INFDEV

General idea

Classes as data structures with methods

> TEAM INFDEV

Introduction

- To solve the problem, we will create classes
- A class is the union of a data structures and its characterizing functions
- The functions inside a class are known as methods

Classes as data structures with methods

> TEAM INFDEV

Blueprint of a class

- What are the fundamental attributes?
- What properties do the attributes have (relationships, etc.)?
- What are the fundamental methods of the class?
- What properties do the methods have (relationships, returned values, etc.)?

The blueprint of the list class (**THIS IS NOT CODE!**)

Classes as data structures with methods

> TEAM INFDEV

```
Abstraction List =
  the list may be Empty, with
    no attributes
    IsEmpty() method returns True
    Length method returns 0
   Map(f) method returns the empty list
    Filter(p) method returns the empty list
    . . .
  the list may be a Node
    head attribute (the value of the element of this node)
    tail attribute (the rest of the list)
    IsEmptv() method returns False
    Length method returns the length of the list
    Map(f) method returns the the transformed list wrt function f
    Filter(p) method returns the list with only elements respecting p
    . . .
```

10/1

Classes as data structures with methods

> TEAM INFDEV

- The hardest part of building a class is its design
- How do we build a reasonable class?
- What is a bad implementation?

Classes as data structures with methods

> TEAM INFDEV

Design of a class

- The same logic that applies to the design of functions applies to classes
- Encapsulation^a is the central property of both
- A class is well encapsulated if
 - it offers a clear interaction surface by not exposing its internals in a dangerous way
 - it is a cohesive unit that offers a single, clearly defined set of related services

^aAlso called information hiding

Classes as data structures with methods

> TEAM INFDEV

- Thanks to encapsulation, a program can be built as a series of independent units
- These units are loosely coupled, in the sense that a change in the implementation (but not the methods offered) of one unit does not break the others^a

^aThink about a faster implementation, for example.

Classes as data structures with methods

> TEAM INFDEV

- A bad example would be a ListOrPlayer class which contains a list or a player, with methods and fields such as:
 - IsList, IsPlayer
 - Name, Score, Weapon, ...
 - Length, Map, Filter, ...
- Why is it a bad example?

Classes as data structures with methods

> TEAM INFDEV

- A bad example would be a ListOrPlayer class which contains a list or a player, with methods and fields such as:
 - IsList, IsPlayer
 - Name, Score, Weapon, ...
 - Length, Map, Filter, ...
- Why is it a bad example?
- Because it is not a clear unit, but two at the same time

Classes as data structures with methods

> TEAM INFDEV

- A bad example would be a List which leaks parts of implementation
- A "leaky" list would have strange methods that rely on specific external usage patterns like:
 - ComputeFirstPartOfLength that computes the length of the first half of the list
 - ComputeSecondPartOfLength that computes the length of the second half of the list
 - GetLengthParts that returns the lengths of the two half lists
- Why is it a bad example?

Classes as data structures with methods

> TEAM INFDEV

- A bad example would be a List which leaks parts of implementation
- A "leaky" list would have strange methods that rely on specific external usage patterns like:
 - ComputeFirstPartOfLength that computes the length of the first half of the list
 - ComputeSecondPartOfLength that computes the length of the second half of the list
 - GetLengthParts that returns the lengths of the two half lists
- Why is it a bad example?
- Because the implementation of length only happens if the user of the list calls it properly

Classes as data structures with methods

> TEAM INFDEV

Technical details

Classes as data structures with methods

> TEAM INFDEV

Introduction

- We have already seen how we can define a class in Python, just without methods (beside __init__)
- Adding methods is surprisingly simple
- Simply declare a function within the class body, with the usual syntax
 - The function must^a have a special parameter self, which is the first parameter

^aThere are exceptions, we discuss them later.

Classes as data structures with methods

> TEAM INFDEV

```
class Empty:
    def IsEmpty(self):
        return True
    def Length(self):
        return 0
```

Introduction

Classes as data structures with methods

> TEAM INFDEV

```
class Empty:
  def IsEmpty(self):
    return True
  def Length(self):
    return 0
```

Introduction

Notice the self parameter of each method

class Node:
  def IsEmpty(self): return False
  def __init__(self, x, xs):
    self.head = x
    self.tail = xs
  def Length(self):
    return 1 + self.tail.Length()
```

Introduction

• Notice the self parameter of each method

Classes as data structures with methods

> TEAM INFDEV

Using classes

- Usage of classes remains quite intuitive
- Instance a class by using its name and giving parameters that will end up in __init__
- The returned class can be assigned to a variable
- The methods and attributes of the class can be called with

 between the instance of a class and the
 method/attribute name

Actual class usage

Classes as data structures with methods

> TEAM INFDE\

> > l = Node(1, Empty())
> > print(l.Length())

Classes as data structures with methods

> TEAM INFDEV

Constructor

- You may now have realized that __init__ is just another method^a, the constructor of a class
- It is called transparently when creating an instance of a class
- We call it with a parameter less (self), which is given automatically by Python as a new empty container
- Node(1,Empty()) invokes the constructor with two parameters, self is implicit

^aA special one, in that it is called automatically by Python, but a regular method nonetheless

Classes as data structures with methods

> TEAM INFDEV

Methods

- Methods work like the constructor
- We call them with a parameter less (self), which is given automatically by Python as the object from which the method was called
- 1.Length() calls method Length with zero parameters, self is implicitly passed as 1

Classes as data structures with methods

> TEAM INFDEV

Syntax and semantics of methods

- The only new element of semantics is indeed the passing of self
- This is described with a code transformation that happens at runtime
- Method call is not really a new feature, but rather a handy way to use existing features

Classes as data structures with methods

> TEAM INFDEV

Syntax and semantics of methods

- Whenever Python encounters a call such as x.M(p1, ..., pn) then it transforms it into a similar call C.M(x, p1, ..., pn) where C is the type of x in memory
- This way x automatically becomes self inside M

$$\langle x.M(p_1,\ldots,p_n),S,H\rangle \to \langle H[S[x]][C].M(x,p_1,\ldots,p_n)\rangle$$

• This presupposes that the heap contains, for each class, an additional attribute C that is the class of declaration

 n	
 $[; C \mapsto TypeOfInstance]$	

Classes as data structures with methods

> TEAM INFDEV

Syntax and semantics of methods

- Methods defined with a self parameter are called instance methods
- Using them is bound to the calling context (represented by self)
- Some methods can be defined without a self parameter
- Such methods are called static methods, because they are independent of a specific instance

Classes as data structures with methods

> TEAM INFDEV

Syntax and semantics of methods

- Static methods are used by specifying the name of the class to which the method belongs to C.M(p1,...,pn)
- There is nothing special about them, they just behave like any function call
- They are useful to group functionality related to a single class that is not related to the class instances

Classes as data structures with methods

> TEAM INFDEV

Special method names

- Some special method names are reserved by Python
- These names represent operators that are automatically called by Python
- A typical example is __str__, which is automatically invoked whenever print or str are used

Classes as data structures with methods

> TEAM INFDEV

Special method names

- Other special names represent operators
- For example:
 - __le__ is called whenever x <= y was used
 - __add__ is called whenever x + y was used
 - __lshift__ is called whenever x << y was used
 - ..

Classes as data structures with methods

> TEAM INFDEV

Examples

- Let's begin with a simple example
- A counter that keeps track of how many times some event has happened
- The constructor of the counter starts the count at zero
- A Tick method increments the count
- A pretty printer to nicely format instances when they are output

"Counter" example

Classes as data structures with methods

> TEAM INFDEV

```
class Counter:
    def __init__(self):
        self.cnt = 0
    def Tick(self, n):
        self.cnt = self.cnt + n
    def __str__(self):
        return "Tickedu" + str(self.cnt) + "utimes."

c = Counter()
    for i in range(0, 20):
        c.Tick(i)
        print(c)
```

What does this program do?

"Counter" example

Classes as data structures with methods

> TEAM INFDEV

```
class Counter:
    def __init__(self):
        self.cnt = 0
    def Tick(self, n):
        self.cnt = self.cnt + n
    def __str__(self):
        return "Tickedu" + str(self.cnt) + "utimes."

c = Counter()
for i in range(0, 20):
    c.Tick(i)
    print(c)
```

What does this program do?

Prints the "ticked" message for 0, 1, 3, 6, 10

Classes as data structures with methods

> TEAM INFDEV

Examples

- Let's move to an almost full implementation of lists
- Lists come in two flavours: Empty, and Node
- We want at least the following methods:
 - IsEmpty
 - String conversion
 - << to create lists more easily</p>
 - Sum to add all elements of the list
 - Length to find the list length
 - Map to transform all elements of the list
 - Filter to remove some elements of the list
 - Fold to collapse the list

Let's start with the empty list

Classes as data structures with methods

```
class Empty:
  def IsEmpty(self): return True
  def __str__(self):
    return "[]"
  def rlshift (self. v):
    return Node(v. self)
  def Sum(self):
    return 0
  def Length(self):
    return 0
  def Map(self,f):
    return self
  def Filter(self,p):
    return self
  def Fold(self.f.z):
    return z
Empty = Empty()
```

The non-empty list

Classes as data structures with methods

```
class Node:
 def IsEmpty(self): return False
 def Head(self): return self.head
 def Tail(self): return self.tail
 def init (self. x. xs):
    self.head = x
    self.tail = xs
 def rlshift (self. v):
    return Node(v, self)
 def __str__(self):
    return str(self.head) + "<<" + str(self.tail)
 def Sum(self):
    return self.head + self.tail.Sum()
 def Length(self):
   return 1 + self.tail.Length()
 def Map(self,f):
    return Node(f(self.head), self.tail.Map(f))
 def Filter(self.p):
   xs = self.tail.Filter(p)
    if p(self.head):
      return Node(self.head. xs)
    else:
      return xs
 def Fold(self.f.z):
    return f(self.head. self.tail.Fold(f.z))
```

Classes as data structures with methods

> TEAM INFDEV

Assignments

- Find the implementation (or the slides) online and open them to reference Node and Empty
- What does 1 = 1 << (2 << (3 << (4 << Empty))) do?

Classes as data structures with methods

> TEAM INFDEV

Assignments

- Find the implementation (or the slides) online and open them to reference Node and Empty
- What does l = 1 << (2 << (3 << (4 << Empty)))
 do?
 - It creates list Node(1, Node(2, Node(3, Node(4, Empty))))
- Why did we write Empty instead of Empty()?

Classes as data structures with methods

> TEAM INFDEV

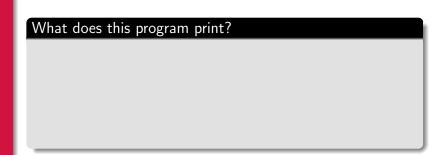

Assignments

- Find the implementation (or the slides) online and open them to reference Node and Empty
- What does l = 1 << (2 << (3 << (4 << Empty)))
 do?
 - It creates list Node(1, Node(2, Node(3, Node(4, Empty))))
- Why did we write Empty instead of Empty()?
 - Aesthetics: we define a single instance of Empty = Empty() to avoid recalling the constructor every time

Using lists

Classes as data structures with methods

Using lists

Classes as data structures with methods

> TEAM INFDEV

What does this program print?

- 'length(1<<2<<3<<4<<[]) = 4'
- 'incr(1<<2<<3<<4<<[]) = 2<<3<<4<<5<([]'
- 'even(<1<<2<<3<<4<<[]) = 2<<4<<[]'
- 'sum(1<<2<<3<<4<<[]) = 10'
- 'mul(1<<2<<3<<4<<[]) = 24'

Classes as data structures with methods

> TEAM INFDEV

Let's see build a 2D vector

- We want things to move over the screen
- We define 2D vectors to store the position of objects
- 2D vectors contain only X, Y attributes
- Methods are:
 - Vector addition, subtraction, negation, multiplication by scalar
 - Length of the vector (according to Pythagoras' theorem)
 - Some static methods to get some special vectors (null, (0,1), (1,0)

Implementation of vector 2D

Classes as data structures with methods

```
class Vector2:
 def __init__(self, x, y):
   self.X = x
   self.Y = v
 def Length(self):
   return math.sqrt(self.X * self.X + self.Y * self.Y)
 def neg (self):
   return Vector2(-self.X, -self.Y)
 def __add__(self, other):
   return Vector2(self.X + other.X, self.Y + other.Y)
 def sub (self. other):
   return self + (-other):
 def __mul__(self, k):
   return Vector2(self.X * k, self.Y * k)
 def str (self):
   return "(" + str(self.X) + "," + str(self.Y) + ")"
 def Zero():
   return Vector2(0.0, 0.0)
 def UnitX():
   return Vector2(1.0, 0.0)
 def UnitY():
   return Vector2(0.0, 1.0)
```

Let's build a 2D vector

Classes as data structures with methods

> TEAM INFDEV

```
v = Vector2.UnitX() * 10.0 - Vector2.UnitY() * 2.0
print(v)
```

What does this program print?

Let's build a 2D vector

Classes as data structures with methods

> TEAM INFDEV

```
v = Vector2.UnitX() * 10.0 - Vector2.UnitY() * 2.0
print(v)
```

What does this program print?

(10.0, -2.0)

Classes as data structures with methods

> TEAM INFDEV

Let's make a car

- A car has a Position and a Velocity, both Vector2's
- A car also has Gas in the tank
- A car can Travel: Position moves forward, Gas is burned

Implementation of car

Classes as data structures with methods

Let's build a car!

Classes as data structures with methods

```
c = Car(Vector2.Zero(), Vector2.UnitX(), 10.0)
while(c.Gas > 0.0):
    c.Travel(2.0)
print(c)
```

```
What does this program print?
```

Let's build a car!

Classes as data structures with methods

> TEAM INFDEV

```
c = Car(Vector2.Zero(), Vector2.UnitX(), 10.0)
while(c.Gas > 0.0):
    c.Travel(2.0)
print(c)
```

What does this program print?

- A car at (2.0,0.0) with a tank of 8.0 liters
- A car at (4.0,0.0) with a tank of 6.0 liters
- A car at (6.0,0.0) with a tank of 4.0 liters
- A car at (8.0,0.0) with a tank of 2.0 liters
- A car at (10.0,0.0) with a tank of 0.0 liters

Classes as data structures with methods

> TEAM INFDEV

A few advanced design topics

Classes as data structures with methods

> TEAM INFDEV

General idea

- There are countless ways to design classes
- Each of these has advantages and disadvantages
- It is a design discipline, and as such "artsier" than strictly needed
- Experience will show the way
- For the moment, we just illustrate one such possibility

Classes as data structures with methods

> TEAM INFDEV

Immutable and mutable classes

- Not all classes modify the values of their attributes as methods are called
- Some classes can be designed to be immutable
- An instance never changes values after creation
- Methods return a new instance with the new attribute values instead of changing the attribute values of the starting instance

Classes as data structures with methods

> TEAM INFDEV

Immutable and mutable classes

- Never changing attributes is a powerful technique
- Sharing of instances is safer, because unexpected changes will never happen
- Can you think of examples when this might be useful?

Classes as data structures with methods

> TEAM INFDEV

Immutable and mutable classes

- Never changing attributes is a powerful technique
- Sharing of instances is safer, because unexpected changes will never happen
- Can you think of examples when this might be useful?
- Breaking another class which assumes that the given instance will always remain as expected
- Multiple threads
- Rollback/checkpoints/transactional systems
- ...

Classes as data structures with methods

> TEAM INFDEV

Let's make an immutable car

- A car has a Position and a Velocity, both Vector2's
- A car also has Gas in the tank
- A car can Travel: a new car is returned where Position is moved forward, Gas is burned

Implementation of an immutable car

Classes as data structures with methods

Let's build an immutable car!

Classes as data structures with methods

> TEAM INFDEV

```
c = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0)
while(c.Gas > 0.0):
    c = c.Travel(2.0)
print(c)
```

What does this program print?

Let's build an immutable car!

Classes as data structures with methods

> TEAM INFDEV

```
c = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0)
while(c.Gas > 0.0):
    c = c.Travel(2.0)
print(c)
```

What does this program print?

- A car at (2.0,0.0) with a tank of 8.0 liters
- A car at (4.0,0.0) with a tank of 6.0 liters
- A car at (6.0,0.0) with a tank of 4.0 liters
- A car at (8.0,0.0) with a tank of 2.0 liters
- A car at (10.0,0.0) with a tank of 0.0 liters

Classes as data structures with methods

> TEAM INFDEV

Rolling back time

- Suppose we stored the initial value of the car c0 = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0) before the loop
- Then we just run the loop
- Can we "roll back time" by going back to the initial value of the car?

Classes as data structures with methods

> TEAM INFDEV

Rolling back time

- Suppose we stored the initial value of the car c0 = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0) before the loop
- Then we just run the loop
- Can we "roll back time" by going back to the initial value of the car?
- Yes!
- Was this possible with the first implementation?

Classes as data structures with methods

> TEAM INFDEV

Rolling back time

- Suppose we stored the initial value of the car c0 = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0) before the loop
- Then we just run the loop
- Can we "roll back time" by going back to the initial value of the car?
- Yes!
- Was this possible with the first implementation?
- No!

Rolling back time

Classes as data structures with methods

> TEAM INFDEV

```
c = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0)
c0 = c
while(c.Gas > 0.0):
    c = c.Travel(2.0)
    print(c)
print(c0)
```

What is stored in co?

Rolling back time

Classes as data structures with methods

> TEAM INFDEV

```
c = ImmutableCar(Vector2.Zero(), Vector2.UnitX(), 10.0)
c0 = c
while(c.Gas > 0.0):
    c = c.Travel(2.0)
    print(c)
print(c0)
```

What is stored in c0? The initial value of the car, unchanged!

Classes as data structures with methods

> TEAM INFDEV

Choices, choices

- Why would you use one design instead of the other?
- Mutable classes have
 - the advantage that they are simple to build and intuitive
 - the disadvantage that they are "destructive", in the sense that all modification destroys previous information that might still be in use
- Immutable classes have
 - the advantage that they are not destructive
 - the disadvantage that they are more complex to build and structure
- Mutable classes for current state of an object
- Immutable classes for things that are not supposed to change (vectors, numbers) or that might need to be rolled back

Classes as data structures with methods

> TEAM INFDEV

Conclusion

Conclusion

Classes as data structures with methods

> TEAM INFDEV

Lecture topics

- In this lecture we have "closed the circle" of data structures and functions
- We have defined classes as the joining of functions and data structures
- We have seen a series of class implementation examples in action
- We have discussed different design balances that might come into consideration when choosing the structure of a class

This is it!
